ON COMPLETIONS OF UNIFORM LIMIT SPACES

by Oswald Wyler

Weil and Bourbaki [1] introduced the category of uniform spaces, to be

\mathcal{U}

1 *

denoted by \mathcal{U} ; in this note, we constructed a coreflective completion functor from \mathcal{U} to the subcategory \mathcal{U}^c of separated complete uniform spaces. Cook and Fischer [2] introduced the category of uniform limit spaces which we shall denote by \mathcal{J} . They pointed out that \mathcal{J} can be regarded as a coreflective full subcategory of \mathcal{U} . Subsequently, the author [3] constructed a coreflective completion functor from the subcategory of separated uniform limit spaces to the smaller subcategory \mathcal{J}^c of separated complete uniform limit spaces* Cochran [4] studied this completion further, supplying the proofs not given in [3]. He also raised the following question* A uniform space (E, \mathcal{J}) has a completion (E, \mathcal{J}^c) in \mathcal{J}^c and also the Bourbaki completion (E^0, \mathcal{J}) in \mathcal{J}^{pc} . How are these two completions related? We answer this question in the present note by showing that \mathcal{J}^c is the finest uniform structure of E coarser than the uniform limit structure \mathcal{J}^c .

We introduce first the notations and definitions which we shall use. If \mathcal{J} and \mathcal{K} are filters on a set B , we put $\mathcal{J} \leq \mathcal{K}$ if \mathcal{J} is finer than \mathcal{K} , i.e. if $\mathcal{J} \subset \mathcal{K}$. With this order relation, filters on E form a complete lattice. If \mathcal{J} and \mathcal{K} are filters on E , then $\mathcal{J} \vee \mathcal{K}$ consists of all sets $A \cup B$,

$A \in \mathcal{Z} \gg B \in \mathcal{F}$ and $L \in \mathcal{I}$ consists of all sets $A \cap B$, $A \cup B$, $B \setminus A$.

We shall use the following notations for filters on $E \times E$. If \mathcal{F} and \mathcal{G} are filters on E , we denote by $\mathcal{F} \times \mathcal{G}$ the filter on $E \times E$ generated by all sets $A \times B$, $A \in \mathcal{F}$, $B \in \mathcal{G}$. For subsets U and V of $E \times E$, we denote by \mathcal{J}^1 the set of all pairs (y, x) with $(x, y) \in U$, and by $U \circ V$ the set of all pairs (x, z) with $(x, y) \in U$ and $(y, z) \in V$ for some y . For filters \mathcal{U} and \mathcal{V} on $E \times E$, we denote by $\mathcal{U} \wedge \mathcal{V}$ the filter consisting of all sets $U \cap V$, $U \in \mathcal{U}$, $V \in \mathcal{V}$, and by $\mathcal{U} \circ \mathcal{V}$ the filter generated by all sets $U \circ V$, $U \in \mathcal{U}$, $V \in \mathcal{V}$. We refer to f2j and f3j for the laws satisfied by these operations*

Cook and Fischer [3] have defined a uniform limit structure on a set E as a set \mathcal{F} of filters on $E \times E$ with the following three properties*

UL 1. If $\mathcal{U} \in \mathcal{F}$ and $\mathcal{V} \in \mathcal{F}$ then $\mathcal{U} \wedge \mathcal{V} \in \mathcal{F}$.

UL 2. Let \mathcal{A} be the filter of all subsets of $E \times E$ containing the diagonal Δ of E . If $\mathcal{U}, \mathcal{V} \in \mathcal{F}$, then $(\mathcal{U} \circ \mathcal{V}) \circ \mathcal{A} \in \mathcal{F}$.

DL 3. If $\mathcal{C} \in \mathcal{I}$, then $\mathcal{C} \wedge \mathcal{F} \in \mathcal{F}$.

A uniform limit space is a pair (E, \mathcal{F}) consisting of a set E and a uniform limit structure \mathcal{F} on E . The filters of \mathcal{F} are called uniform filters of (E, \mathcal{F}) .

A uniformly continuous mapping $f : (E, \mathcal{F}) \rightarrow (E', \mathcal{F}')$ of uniform limit spaces is a mapping $f : E \rightarrow E'$ such that the filter $(f \times f)(\mathcal{U})$ is in \mathcal{F}' for every filter \mathcal{U} in \mathcal{F} . Uniform limit spaces and their uniformly continuous mappings are the objects and morphisms of a category which we denote by $\mathcal{J}\mathcal{U}$ and call the category of uniform limit spaces.

Since $(\mathcal{U} \circ \mathcal{V}) \circ \mathcal{A} \in \mathcal{F}$, it follows from

the axioms UL that $(P^{\wedge}J^{\wedge}$ and $(p \wedge y$ are in \mathcal{F} whenever $(p_f^{\wedge}$ are in \underline{J} ,

*

5

and that $A \in \mathcal{F}$. Thus \mathcal{F} is a dual filter of filters on $E \times B$.

If \mathcal{F} is a principal dual filter, i.e. \mathcal{F} consists of all filters (\mathcal{F}) such that $(P \mathcal{F} < t^*$, for a generator $(p$ of j ; , then $(p_0$ is the filter of entourages of a uniform structure of E . All uniform structures are obtained in this way; see f?). This means that we may (and do) regard the category of uniform

spaces as a full subcategory of JJ % we denote this subcategory by JJ . For any uniform limit space $(E_{fi}j)$ there is, as shown in f2L a finest uni-

form structure \mathcal{F}^p on E such that $\mathcal{F} \wedge J_{\underline{J}}^p$ (i.e. $\mathcal{F} \subset J_{\underline{J}}^p$). If $(\mathcal{F}_y$ is the filter of entourages of $(E_{\underline{J}}; J_{\underline{J}}^p)$, then $(\mathcal{F}) < \mathcal{F}(\mathcal{F}_y$ for every filter $(p$ of \mathcal{F} , but as Cochran f2] has pointed out, (\mathcal{F}_0) is in general not the supremum of all filters in \underline{J} . The correspondence from (B, \underline{J}) to $(E_{\underline{J}}; J_{\underline{J}}^p)$ defines a coreflective functor from JJ to JJ^p , as shown in f3j.

We shall need the following additional definitions. Let $(E_{f<}j)$ be a uniform limit space. A filter \mathcal{F} on B is called a Cauchy filter of (E, \mathcal{F}) if $j\mathcal{F}$ is not the null filter⁴ of B , and $\underline{J}P \times jP (5\mathcal{F}$. Two Cauchy filters \mathcal{F} and \mathcal{G} on B are called equivalent if $\underline{P} K \mathcal{F} \in \underline{J}$. This is easily seen to be an equivalence relation. We denote by E the set of all equivalence classes of Cauchy filters of $(B, \mathcal{F})_{\mathcal{F}}$ and by $q(p)$ the equivalence class of a Cauchy filter \mathcal{F} .

For $x \in E_{\mathcal{F}}$ we denote by x^* the filter of all sets $A \subset Z E$ with $x \mathcal{F}. A$. This is a Cauchy filter. We say that a filter \underline{F} on B converges to $x \in E$ if $\underline{J}P \times x^* \subset j$. This defines the induced limit space⁶ of (E, \underline{J}) ; see f3J. Every convergent filter on E is a Cauchy filter. The uniform limit space $(E_{fi}j)$ is

called complete if, conversely, every Cauchy filter converges to some point of E .

We call (E, \mathcal{J}) separated if $x \neq y \in \mathcal{J}$, for points x, y of E_f only if $x \gg y$.

We denote by $\overline{\mathcal{J}}^c$ the subcategory of separated complete uniform limit spaces and their uniformly continuous mappings. As shown in [2], $\overline{\mathcal{J}}^c$ is basically the same as the category of separated (i.e. Hausdorff) limit spaces. We denote by $\overline{\mathcal{J}}^{pc}$ the intersection of the subcategories $\overline{\mathcal{J}}^p$ and $\overline{\mathcal{J}}^c$ of $\overline{\mathcal{J}}$.

For any uniform limit space $(E_f, \mathcal{J}) \in \overline{\mathcal{J}}^c$ we construct a separated complete uniform limit space (E, \mathcal{J}^c) as follows. E is the set of equivalence classes of Cauchy filters of (E_f, \mathcal{J}) . We define $j : E \rightarrow E^o$ by putting $j x = q(x)$ for $x \in E$. For a Cauchy filter \mathcal{J}^c of (E, \mathcal{J}^c) and $j \mathcal{J}^c \sim \langle p(F) \rangle$; we put

$$y \in \mathcal{J}^c \Leftrightarrow (j \mathcal{J}^c) \wedge \mathcal{J} \in \mathcal{J}^c.$$

With these notations, \mathcal{J}^c is the dual filter of filters on $E \times E$ generated by all filters of the form

$$(j \times j)(\mathcal{J}) \cup \Delta_c \cup \gamma \mathcal{F}_1 \cup \dots \cup \gamma \mathcal{F}_r,$$

where $\beta \in \mathcal{J}$, Δ_c is the diagonal of $E \times E$ and $\mathcal{F}_1, \dots, \mathcal{F}_r$ are Cauchy filters of (E_f, \mathcal{J}) . As pointed out in [5] the following theorem is valid.

Theorem 1. For any uniform limit space $(E_f, \mathcal{J}) \in \overline{\mathcal{J}}^c$, (E, \mathcal{J}^c) is a separated complete uniform limit space, and the mapping $j : (E_f, \mathcal{J}) \rightarrow (E, \mathcal{J}^c)$ is uniformly continuous. Moreover, whenever $f : (E_f, \mathcal{J}) \rightarrow (E^f, \mathcal{J}^f)$ is uniformly continuous and (E^f, \mathcal{J}^f) separated and complete, then there is a unique uniformly continuous mapping $f^c : (E, \mathcal{J}^c) \rightarrow (E^f, \mathcal{J}^f)$ such that $f^c \circ j = f$.

In other words, Theorem 1 states that the correspondence from (B, j) to (E_{fJ}) defines a coreflective functor from JJ to the subcategory tJ . We refer to [2] for the proof. In [5], only separated uniform limit spaces (B, \mathcal{E}) were considered, but the extension to the general case is trivial. The only change is this. If (B_{fj}) is separated, and only in this case, $j : (E, \mathcal{C}) \rightarrow (E^c, \mathcal{E}^c)$ induces an isomorphism of (B_{fj}) and a dense subspace of $(B_{fj}^{c,c})$.

For a uniform space (E, J) , with filter \mathcal{C} of entourages, we have of course the completion (E^c, J^c) , and the finest uniform structure J^{cp} of E^c which is coarser than \mathcal{E}^c . We also have the itoubaki completion $j : (E, \mathcal{E}) \rightarrow (E^c, \mathcal{E}^c)$ constructed as follows. The set E^c and the mapping $j : E \rightarrow E^c$ are the same as for (E^c, J^c) . For an entourage $U \in \mathcal{C}$, let U^b be the set of all pairs (f, V) $f \in E \times E^c$ such that there are Cauchy filters \mathcal{F} and \mathcal{G} of (E, J) with $I \ll \mathcal{F} / W = \mathcal{G}$, and $U \cap \mathcal{F} \times \mathcal{G}$. The filter of entourages \mathcal{O}^b of (E^c, J^b) is generated by the sets U^b , $V \in \mathcal{E} : 0$.

Lemma $jJ \wedge \wedge jJ$.

Proof $\mathcal{E} \wedge \mathcal{E}^{cp}$ is clear. For $j : E \rightarrow E^c$ there is, by Theorem 1, a uniformly continuous mapping $j^c : (E^c, J^c) \rightarrow (B_{fj}^{c,b})$ such that $j \gg j^c j$. For a Cauchy filter \mathcal{F} of (E, J) , the filter $j\mathcal{C}j$ converges to $q(\mathcal{F})$ in (E^c, J^c) and in (E^c, J^b) and thus $j^c(q(\mathcal{F})) = q(\mathcal{F})$. Thus j^c is the identity mapping, and $j^c \wedge j^c$ follows. Since \mathcal{E} is principal, also $\mathcal{E} \wedge J^b$.

Theorem j? If (E, J) is a uniform space, then the uniform structure J^b of E^c is the finest principal structure J^{cp} coarser than the uniform limit

structure $\mathcal{J}^c \cdot \mathcal{J}^b$ is the supremum of all filters \mathcal{P}^c and (\mathcal{P}^b) the filter of entourages of \mathcal{J}^b , then $(\mathcal{P}^b)^* \circ \mathcal{J}^c \circ \mathcal{J}^b \approx \mathcal{P}^c$

Proof. If \mathcal{O}^P is the filter of entourages of \mathcal{J}^{CP} , then $\mathcal{J}^c \circ \mathcal{O}^P \circ \mathcal{J}^b$ and $(\mathcal{J}^c)^P \circ \mathcal{O}^P \circ (\mathcal{J}^b)^P$. Thus $\mathcal{J}^c \circ \mathcal{O}^P \circ \mathcal{J}^b \approx \mathcal{O}^P$, and $\mathcal{O}^b \circ \mathcal{J}^c \circ \mathcal{J}^b \approx \mathcal{O}^b$ implies that $(\mathcal{J}^c)^h \circ \mathcal{O}^P \circ \mathcal{J}^b \approx \mathcal{O}^V$, and hence $\mathcal{J}^{CP} \ll \mathcal{J}^b$.

Let now $V \in \mathcal{I}$. Since $(j \times j)(\mathcal{U}) \in \mathcal{I}$, and $\mathcal{U} \circ \mathcal{U} \in \mathcal{I}$ for every Cauchy filter \mathcal{U} of (B, \mathcal{J}) , there is an entourage $U \in \mathcal{U}$ such that $(j \times j)(u) \subset V$, and for every Cauchy filter \mathcal{E} of (E, \mathcal{J}) and $\mathcal{J}^c \ll q(\mathcal{E})$ there is a set $A \in \mathcal{J}^c$ such that $A^1 \times A^1 \subset V$ for $A^1 \in \mathcal{J}(A) \circ \mathcal{U}^{\wedge}$. Now consider $(\mathcal{J}^c \circ \mathcal{J}^b) \in \mathcal{U}^b$.

There are Cauchy filters \mathcal{E} and \mathcal{F} of (B, \mathcal{J}) and sets $A \in \mathcal{J}^c$, $B \in \mathcal{E}$ such that $\mathcal{E} \approx q(\mathcal{F})$, $\mathcal{F} \approx q(\mathcal{E})$, and $A \times B \subset U$. Replacing A and B by smaller sets of \mathcal{P} and \mathcal{E} if necessary, we can assume that $A^1 \times A^1 \subset V$ and $B^1 \times B^1 \subset V$ for $A^1 \in \mathcal{J}(A) \circ \mathcal{U}^{\wedge}$ and $B^1 \in \mathcal{J}(B) \circ \mathcal{U}^{\wedge}$. Thus if $x \in A$ and $y \in B$, then $(\mathcal{E}, j(x)) \in \mathcal{V}$, $(\mathcal{F}, j(y)) \in \mathcal{V}$, and $(j(y), \mathcal{F}) \in \mathcal{V}$. But then $(j \sim, \mathcal{U})$ is in $\mathcal{V} \circ \mathcal{V} \circ \mathcal{V}$, and thus $\mathcal{U}^b \subset \mathcal{V} \circ \mathcal{V} \circ \mathcal{V}$. As the sets $\mathcal{V} \circ \mathcal{V} \circ \mathcal{V}$, $\mathcal{V} \in \mathcal{E} \circ \mathcal{X} \circ \mathcal{I}$, generate $\mathcal{S} \circ \mathcal{S} \circ \mathcal{S} \circ \mathcal{S} \circ \mathcal{S}$ we have proved (I) $\mathcal{J}^c \circ \mathcal{J}^b \approx \mathcal{O}^b$ and hence the Theorem.

A simple example shows that the equation $\mathcal{S} \circ \mathcal{S} \circ \mathcal{S} \approx \mathcal{O}^b$ cannot be improved in general*. If (E, \mathcal{J}) is the set of rational numbers with the usual uniform structure, then (B^c, \mathcal{J}^b) is the set of real numbers with the usual uniform structure*. In this case, $\mathcal{S} \circ \mathcal{S}$ is strictly finer than $\mathcal{S} \circ \mathcal{S} \circ \mathcal{S}$ and $\mathcal{J}^c \circ \mathcal{J}^b$ is strictly finer than the filter (\mathcal{P}^b) of entourages of the real numbers. We leave the details of this to the reader.
