5. Appendix: Other (b,d)-sequences

Suppose Y is a (b,d) -sequence for A , where (b,d) is an \wedge -pair such that $\text{supp } (b)$ is infinite, but Y is not subcomplete. Is it still possible to infer the existence of a closed (b,d) -sequence "near" Y ? An obvious candidate is $\text{cl } Y$, where $(\text{cl } Y)(n) = \text{cl}(Y(n))$, $n \in \text{co}$; but even if we could show that $\text{cl } Y$ is covariant (see Remark after Lemma 5.1), it might not be true that $\text{cl } Y \subset X_{\text{Od}}$. We therefore proceed indirectly, first constructing a subcomplete (b,d) -sequence with suitable properties. The desirability of this investigation was suggested by results of G. Pecelli concerning dichotomies for functional-differential equations.

Let us recall [1; Lemma 6.3] for given deb/\dots : For each $m \in \text{co}$ the set $X_{r,m}$, of \tilde{d} -solutions of (I_r, \dots) is a feubspace of $\tilde{d}_{[m]}(X)$ and the linear mapping $\Pi(m) : X_{r,m} \rightarrow X_{\text{Od}}(m)$ is bounded and bijective.

Let Y be a covariant sequence, $Y \subset X_{\text{Od}}$. For each $m \in \text{co}$ we set $Y_{\text{cl}}(m) = \Pi(m) (\text{cl}_{\tilde{d}_{[m]}} (\Pi(m)^{-1}(Y(m))) \subset X_{r,m} = X_{\text{Od}}(m)$, where cl^{\wedge} indicates closure in $\tilde{d}_{[m]}(X)$ or, equivalently, in the subspace $X_{r,m}$. Thus Y_{cl} is subcomplete in X and, since $\Pi(m)$ is bounded and its range

includes $Y(\text{ra})_5$

$$(5.1) \quad Y(m) \subset \underset{\sim}{Y_d}(m) \text{ a cl } Y(m) \quad m \in \omega.$$

We observe that the definition of $\underset{\sim}{Y_d}$ may be rephrased as follows: $u \in \underset{\sim}{Y_d}(m)$ if and only if, x being the solution of $(I_{r_{m_j}})$ with $x(m) = u$, there exists for every $\epsilon > 0$ a solution y of $(I_{r_{m_i}})$ in $\underset{\sim}{Y_{r_{m_i}}}$, such that $x - y$ is a $\underset{\sim}{d}$ -solution and $\|x - y\|_{\alpha'} < \epsilon$.

5.1. Lemma, Let Y be a (b, d) -sequence for an \wedge -pair $(b^{\wedge}d)$ such that $\text{supp } (b)$ is an infinite set (in particular, for a \wedge -pair or a \mathcal{F}^{\wedge} -pair $(\mathcal{F}^{\wedge}d)$). Then $\underset{\sim}{Y_d}$ is a subcomplete $(\underset{\sim}{b}, \underset{\sim}{d})$ -sequence.

Proof. It is sufficient to prove that $\underset{\sim}{Y_d}$ is covariant: for then $Y \subset \underset{\sim}{Y_d}$, $\underset{\sim}{Y_d} \subset X$ implies that $\underset{\sim}{Y_d}$ is a $(b^{\wedge}d)$ -sequence [1; Lemma 8.4^(b)], and it is subcomplete by its definition. Let integers $n_{\ast}^{\ast} n_{\ast}^{\ast} \ast > \epsilon$ given with $n \geq n_0 \geq 0$. We are to prove that $(U(n, n_0)) \underset{\sim}{\supset} (\underset{\sim}{Y_d}(n)) = \underset{\sim}{Y_d}(n_0)$.

Let $u \in Y_d(n_0)$ and $\epsilon > 0$ be given, and let x be the solution of (I_{p_n}, \cdot) with $x(n_0) = u$, there exists a solution y of (I_{r_n}, \cdot) in Y_{r_n} , such that $\|x - y\|_d < \epsilon$. But then $\{x_{r_n}\}_{n \geq n_0}$ are solutions of (I_{r_n}, \cdot) , $Y_{r_n}^i$ is in Y_{r_n} , and $\|x_{r_n} - Y_{r_n}^i I_d \otimes I^* - y\|_d < \epsilon$. Therefore $U(n, n_0)u = x(n) = x_{r_n}(n) \in Y_d(n)$, and hence $(U(n, n_0))^{-1}(Y_{fl}(n)) \supset Y_d(n_0)$. It remains to prove the reverse inclusion.

We may choose $n_1 \in \text{supp}(b)$, $n_1 > n_0$. Since, by the preceding part of the proof applied to n_1 , we have

$$(U(n, n_0))^{-1}(Y_d(n)) \subset (U(n, n_0))^{-1}(U(n_1, n_0))^{-1}(Y_{fl}(n_1)) = (U(n_1, n_0))^{-1}(Y_d(n_1))$$

it will be sufficient to prove that

$$(U(n_1, n_0))^{-1}(Y_d(n_1)) \subset Y_d(n_0)$$

Let $\epsilon > 0$ be given. Consider any $u \in (U(n_1, n_0))^{-1}(Y_d(n_1))$ and any $\epsilon > 0$, and let x be the solution of (I_{r_n}, \cdot) with $x(n_0) = u$. Thus $x(n_1) = U(n_1, n_0)x(n_0) \in Y_d(n_1)$. There exists, therefore, a solution y of (I_{f_n}, \cdot) in Y_{f_n} i.e., with $y(n_1) \in Y(n_1)$ and such that $\|x_{r_n} - y\|_d < \epsilon$.

We define $f = (x(n_1) - Y(n_1)) \otimes \dots$, we may, since $n_1 \in \text{supp}(b)$, and find

$$\begin{aligned}
 (5.2) \quad \|f\|_{\tilde{b}} &\leq \|x(n_1) - y(n_1)\| \| \chi^{n_1} \|_{\tilde{b}} \leq \\
 &\leq \|x_{[n_1]} - y\|_{\tilde{d}} \| \chi^{n_1} \|_{\tilde{d}}^{-1} \| \chi^{n_1} \|_{\tilde{b}} < \\
 &< \epsilon \| \chi^{n_1} \|_{\tilde{d}}^{-1} \| \chi^n \|_{\tilde{b}} .
 \end{aligned}$$

Since Y is a (\tilde{b}, \tilde{d}) -sequence, there exists a solution z of (II) with this f such that z lies eventually in Y -- i.e., $zfn^{\wedge} \in Yfn^{\wedge}$ and

$$(5.3) \quad \|z\|_{\tilde{d}} \leq \rho K_Y \|f\|_{\tilde{b}} .$$

Now $z_{r_{L_n 0^j}}$ is a solution of $(II_{L_n 0^j})$ with this f , and so is, obviously $(x_{r_{L_n 0^j}} - y)_{r_{L_n 0^j}}$; also, x is a solution of $(I_{[n_0]})$. Therefore $v = z^{\wedge} - (x^{\wedge} - y)^{\wedge} + x$ is a solution of $(L_{L_n 0^j})$; further, $v(n_{\cdot 1}) = z(n_{\cdot 1}) + y(n_{\cdot 1}) \in Y(n_{\cdot})$, so that v lies in Y_f , and (5.2), (5.3) imply

$$\begin{aligned}
 \|x - v\|_{\tilde{d}} &\leq \|x_{[n_{\cdot}]} - y\|_{\tilde{d}} + \|z\|_{\tilde{d}} < \\
 &< \epsilon(1 + \rho K_Y \| \chi^{n_1} \|_{\tilde{d}}^{-1} \| \chi^{n_1} \|_{\tilde{b}}) .
 \end{aligned}$$

Since $\epsilon > 0$ was arbitrary, it follows that $u = x(n_0) \in Y_d(n_0)$. Hence $(U(n_1, n_0))^{-1}(Y_{f_1}(n_1)) \subset Y_d(n_0)$, as was to be proved.

Remark. A slightly simplified version of the proof will show that the sequence $cl Y$ is also covariant.

5.2. Theorem. Let Y be a (b, d) -sequence for an (b, d) -pair such that $\text{supp } (b)$ is an infinite set (in particular, for a t -pair or a k^*d). Then;

(a) ; if $Y_j(m)$ is closed (in particular, if $Y(m)$ is closed) for some $m \in \mathbb{N}$, then $cl Y = Y_d \wedge a$ closed (b, d) -sequence

(b) ; if $U(n_1, n_0)$ is compact for some $n_1, n_0 \in \mathbb{N}$, $n_1 \wedge n_0 \wedge 0$, then $cl Y = Y_d$ is a closed (b, d) -sequence and its terms have constant finite co-dimension in X .

Proof. Lemma 5.1, formula (5.1), and Theorem 4.1 .
