AZUMAYA ALGEBRAS
AND DERIVATIONS

February, 1971
Introduction

Let $k$ be a field of prime characteristic $p$, $C$ a purely inseparable finite dimensional field extension of exponent 1, and $\Delta$ the restricted $C$-Lie algebra of $k$ derivations in $C$. It was shown by Jacobson that there is a Galois correspondence between subfields of $C$ over $R$ and restricted $C$-Lie subspaces of $\Delta$. In the classical theory of central simple $R$ algebras, where $C$ over $k$ is a Galois extension, group extensions of the multiplicative group of $C$ by the Galois group of $C$ over $k$ give rise, via an appropriate embedding into a ring, to central simple $k$ algebras split by $C$. Hochschild, [5], worked out an analogue of this theorem for the purely inseparable case where the group extensions are replaced by certain regular Lie algebra extensions of $C$ by $D$, $C$ regarded as an abelian Lie algebra. In [8], Jacobson gave a more explicit construction of central simple $k$ algebras split by $C$ using the existence of a derivation $\delta$ in $\Delta$ such that $\text{Ker} \, \delta = k$ and $C[\Delta] = \text{End}_v(C)$. This was generalized by Hoehchsmann in [6] to discuss embeddings of simple $k$ algebras using the 'cyclic' derivation approach of Jacobson.

Recently, S. Yuan [11] has generalized Hochschild's results to purely inseparable commutative ring extensions of exponent 1. It is natural to inquire whether Jacobson's approach can also be generalized to such ring extensions. In this paper we show that indeed it can if we assume the existence of a derivation $\delta$ which will play the role of Jacobson's 'cyclic' derivation. In particular if $R$ is a commutative ring of prime characteristic.
C a purely inseparable commutative R algebra such that C is finitely generated projective as an R module and there exists an R derivation 9 such that Ker g = R and C[d] = End(R)(C), then we obtain Azumaya R algebras split by C (equivalently central separable R algebras split by C) as certain quotients of the ring of differential polynomials over C. We use this result to compute the Chase-Rosenberg group of equivalence classes of Azumaya R algebras split by C and ultimately under additional hypotheses the relative Brauer group of C over R.

The main results in this paper arose from the possibility of interpreting Hochschild's results in a Hopf algebra setting and obtaining Azumaya R algebras via Hopf algebra extensions. We hope to report on this project in a latter paper.
1. Preliminaries

Throughout this paper R will be a fixed commutative ring with unit of prime characteristic p > 0.

Let C be a commutative R algebra and let S be a derivation on C such that Ker S = R. Assume B satisfies a polynomial

\[ X = a_0^t + a_1^{-1} + \ldots + a_{l-1} + \ldots + a_n^t \]

with the \( a_i \) in R. For \( c \) in C denote by \( L_c \) the endomorphism of C effected by multiplication by \( c \). From the formula

\[ (O + L_c)^P = B^P + L(S^{P+1}c + c^P) \]

(\[ 3 \] p.201)

it is easy to see that

\[ X(O + L_c) = L(6c) \]

where

\[ \delta(c) = \sum_{i=0}^{t} a_i \left[ c^P + (\delta c) \cdot \delta^P - \delta \cdot \delta^P + \ldots + (\delta c)^{-1} \right] \]

is an element of R. Furthermore

\[ \delta : C^+ \rightarrow \mathbb{R}^+ \]

is a group homorphism.

Let A be an Azumaya R algebra [4]. Following [11], we call C a splitting subalgebra of A if C is a maximal commutative subalgebra of A such that A is a projective left C module. By [3, Prop, 2.4, p.37] the map \( \psi : C \otimes A^0 \rightarrow ) \) End\(_C\) (A) given by \( \psi(c \otimes a^x = c \cdot a \) is an isomorphism. Let \( A(C,R) \) denote the group of equivalence classes of Azumaya R algebras with splitting subalgebra C, defined in [3,p,38]. We refer the reader to that paper for more details.
2. Rings of differential polynomials

Let $C$ be a commutative $R$ algebra with $3$ a derivation of $C$ such that $\ker S = R$. Assume $C$ is a finitely generated projective $R$ module and $\text{Hom}_R(C^\wedge C) = C[d]$. It is well known that $C$ determines a unique up to order decomposition of $R$ into a direct sum $R = \bigoplus_{i=1}^n R e_i$, the e. orthogonal idempotents such that $Ce_i$ is a finitely generated projective $R e_i$ module of rank $r_i$ with $\text{Hom}(Ce_i, Ce_i) = Ce_i f e_i d U$ [9,p.45]. It follows from [9, Thm.2.4] that $e_d$ satisfies a unique monic polynomial

$$X_i(t) = a_0 t + a_1 t^p + \ldots a^n t^{p^n}$$

with $p^x = r_i a$. Setting $X = SX^t$ in $C[t] = \bigoplus_{i=1}^n Ce_i[t]$ we see that $9$ satisfies a polynomial

$$X(tL) - c t - r a^P - r c a^P + a^P + \ldots a^n t^{p^n}$$

with the $a_i$ in $R$ and $a$ a non-zero idempotent. Furthermore

$$\text{2.2 } (f \in C[t] | f(3) = 0) = X(t)C[t] \quad [9, \text{Cor.2.5}]$$

Let $C[t, d]$ denote the noncommutative ring of differential polynomials with coefficients in $C$ defined by $tc = ct + d(c)$. An easy induction argument shows that

$$t^c = ct^c + B_{r_1} (Bc) t^{r_1} + B_{r_2} U^2 c t^{r_2 - 2} - K c + (a^c c)$$

where we use the notation $B^r_i$ for the binomial coefficients and $r^i$

so $X(t)$ is in the center of $C[t, 9]$ since $t^c = ct^c + 3^p(c)$.

Let $a$ be an element of $R$ and define $C[t^d, B^{a}]$ to be the quotient ring obtained by factoring $C[t, d]$ by the two-sided ideal $J$ generated by $X(t) - a$. Note that since $X(t)^a$ is in
the center of $C[t,a]$, $J = (X(t)-a)C[t,a]$ and

2.3 $C[t,a,a] = \bigoplus_{i=1}^{m} C[t,e_i a, ae_i]$, where we use 2.2 to define $C[e_i t^3, ae_i]$ in the obvious manner.

3. Azumaya R algebras.

In this section we give a complete description of Azumaya R algebras split by $C$ in terms of the rings $C[t,a,a]$ described in the previous section. We remind the reader that the term Azumaya R algebra is equivalent to central separable R algebra.

We begin with a lemma:

Lemma 3.1. Let $C$ be a commutative R algebra with a derivation of $C$ such that $\text{Ker } d = R$. Assume $C$ is a finitely generated projective R module and $\text{Hom}_R(C,C) = C[3]$. Then for any $a$ in $R$, $C[t,a,a]$ is finitely generated projective as a $C$ module and hence as an $R$ module.

Proof: Assume first $C$ is a finitely generated projective $R$ module of rank $r$. Then by [9, Thm.2.4], $a$ satisfies a unique monic polynomial

$$X(t) = a_0 t + a_xt^p + \ldots + a_{i}t^{p} + \ldots + t^p$$

with $p^n = r$. We will show $C[t^9,a]$ is actually free over $C$ of rank $p^n$. By definition $\{t^i | 0 < i \leq p^n\}$ is a left $C$ basis for $C[t^9]$. Since $X(t) - a$ has degree $p^n$ no nontrivial element of $J = (X-a)C[t^*d]$ can have degree less than $p^n$. Hence $(t^i | 0^* i < p^n)$ are $C$ linearly independent and since they clearly generate $C[t^9]$ modulo $J$, they form a basis over $C$ for $C[t^9,a]$. In the general case we have by 2.3 that
\[
\mathcal{C}[t,a,x] = \bigoplus_{i=1}^{m} \mathcal{C}_i[t,e_iB^ae_i]
\]
where \( \mathcal{C}_i \) is a finitely generated projective \( \mathcal{R}_i \) module of rank \( r_i \) and the conditions of the lemma are satisfied for \( \mathcal{R}^Ce^ae^e \). Hence by the first part of the proof, \( \mathcal{C}[t,e_eae^e] \) is a finitely generated projective \( \mathcal{C}_a \) module. Thus \( \mathcal{C}[t,a,a] \) is finitely generated projective as a \( \mathcal{C} \) module. Finally \( \mathcal{C} \) being finitely generated projective as an \( \mathcal{R} \) module implies \( \mathcal{C}[t,d,a] \) is also.

Theorem 3.2. Let \( \mathcal{C} \) be a commutative \( \mathcal{R} \) algebra with \( d \) a derivation of \( \mathcal{C} \) such that \( \text{Ker } d = \mathcal{R} \). Assume \( \mathcal{C} \) is finitely generated projective as an \( \mathcal{R} \) module and \( \text{End}_\mathcal{R}(\mathcal{C}) = \mathcal{C}[g] \). Let \( \mathcal{A} \) be an \( \mathcal{R} \) algebra containing \( \mathcal{C} \). Then \( \mathcal{A} \) is an algebra with \( \mathcal{C} \) as a splitting subalgebra if and only if \( \mathcal{A} \subseteq \mathcal{C}[t;B,a] \) for some \( a \) in \( \mathcal{R} \).

Proof: To show that \( \mathcal{C}[t,a,a] \) is an Azumaya \( \mathcal{R} \) algebra with \( \mathcal{C} \) as a splitting subalgebra it suffices by (2.3) to assume \( \mathcal{C} \) is finitely generated projective of rank \( r \) as an \( \mathcal{R} \) module. In this case the minimal polynomial (2.1) of \( \gamma \) is monic of degree \( p^n = r \). If \( q \) is a prime ideal of \( \mathcal{R} \), it is easy to see that

\[
\mathcal{C}[t,a,a]_q = \mathcal{C}[t,a,a]_q \cong \mathcal{A}_q[t]^l \bigotimes \mathcal{R}_q \bigotimes \mathcal{A}_q[t]^l
\]

where \( \gamma_q \) is the unique extension of \( \gamma \) to \( \mathcal{C}_q \), \( \gamma_q \) is the image of \( \gamma \) under the map \( \mathcal{R} \rightarrow \mathcal{R}_q \) [loc. cit. p. 2]. It follows from [2, p. 180], and Lemma 3.1 that \( \mathcal{C}[t,5,a] \) is an Azumaya \( \mathcal{R} \) algebra if it is one locally at very prime \( q \) of \( \mathcal{R} \). The assertion that \( \mathcal{C} \) is a splitting subalgebra of \( \mathcal{C}[t,3,\alpha_c] \) is again local, hence by (3.3) we need only show that \( \mathcal{C}[t,\gamma,a] \) is an Azumaya \( \mathcal{R} \) algebra with \( \mathcal{C} \) as a splitting subalgebra under the additional hypothesis that \( \mathcal{R} \) is a local ring. In this case \( \mathcal{C} \) is a free \( \mathcal{R} \) module of rank \( r = p^n = \text{degree of minimal polynomial } X(t) \) of \( B_5 \) as in 2.1. In view of Lemma 3.1 we may write every element of \( \mathcal{C}[t,\gamma,a] \) uniquely as a polynomial \( b_0 + b^t + \ldots + b^t \) where \( t < p^m \). Let \( \gamma e \mathcal{C} \) be arbitrary. We have
t^k_c = L_1^k_c \sim B_c \cdot (d^c(t+1))^k-1$, and hence, using the Lie commutator brackets,

\[ [b_Q + b_xt + \ldots + b_j t^c] = \sum_{j=0}^l b_j (t^j_c - ct^j) \]

3.4

\[ = \sum_{j=1}^r b_j \sum_{i=1}^r B_{J_i} (t^i_c) t^{J-i} \]

Note that the last expression is a polynomial in $t$ of degree less than $l$ with constant term $b^{\sim c} + b_3 d (c) + \ldots + b^2 (c)$. Hence for $b = b_1 t + \ldots + b^t$, to commute with all $c$ in $C$ we must have $b_1 t + \ldots + b^t = 0$ for all $c$ in $C$. However it follows easily from (2.2) that the set $\{s^i_{\sim a} : 1 \leq i \leq p\}$ is a $C$-linearly independent set in $\text{End}_C(C)$. Thus the only polynomials in $C[t,\delta,\alpha]$ commuting with elements of $C$ are the zero degree polynomials, the elements of $C$. We conclude that $C$ is a maximal commutative subalgebra of $C[t,\delta,\alpha]$. In addition we have shown that if $b_0 + b_1 t + \ldots + b^t$, is an element of $C[t,\delta,\alpha]$, there exists some element $c$ in $C$ such that $[b + b_1 t + \ldots + b^t, c] = 0$ and the latter is a polynomial in $t$ of degree $< l$. A central element $u$ of $C[t,\delta,\alpha]$ must be in $C$, and in order to commute with $t$ it must have $3(u) = 0$. Hence $u$ is in $R$ and $C[t,\delta,\alpha]$ is central. To show $C[t,\delta,\alpha]$ is separable, observe that $C[t,\delta,\alpha] \otimes R/m \cong C/mC[t,\delta,\alpha]$, where $m$ is the maximal ideal of $R$, $9$ is extended to $C/mC$, and $\overline{\alpha} = a + mC[t,\delta,\alpha]$. Since $C[\ell] = \text{End}_C(C)$, we have $C/mC[a] = \text{End}^\wedge_m (c/mC)$. Let $I$ be a non-zero 2-sided ideal of $C/mC[t,\delta,\alpha]$. Setting $t \equiv t + mC[t,\delta,\alpha]$ we effect the computations in (3.4) for a non-zero element $\overline{b}$ in $I$. By several applications of the Lie bracket with the appropriate elements in $C/mC$ we obtain a non-zero element in $I \cap C/mC$. Since $I \cap C/mC$ is an ideal of $C/mC$ stable under $\alpha$ and $C/mC[a] = \text{End}_\alpha (C/mC)$ this
implies $I D C/mC = C/mC$ which in turn implies $I = C/mC[t^3^a]$. Hence $C/mC[t^9^a]$ is simple and we conclude $C[t^djo]$ is separable by [2, p.180]. Thus $C[t^d,a]$ is an Azumaya $R$ algebra and by lemma 3.1 and the above arguments, $C$ is a splitting subalgebra.

Let $A$ be an Azumaya $R$ algebra containing $C$ as a splitting subalgebra. To finish the proof of theorem 3.2 we need the following lemma, a special case of a more general result proved in [11, Lemma 6].

Lemma. Let $A$ be an Azumaya $R$ algebra containing $C$ as a splitting subalgebra. Then every $R$ derivation of $C$ to itself can be extended to an inner derivation of $A$. 

Thus given an Azumaya R algebra A containing C as a splitting subalgebra, there exists a deA such that cd - dc = \delta(c) for all c in C. We observe that X(d) commutes with every element of C, since cd^a - d^a c = a^a (c) for all i, and hence is an element of C. However since 3(X(d)) =

\[ [X(d),d] = 2^\infty \sum_i d^i \cdot \text{a}^i - \text{a}^i \cdot \text{d}^i \] is an element of R.

It is immediate that we have an R algebra homomorphism from C[t,3,oc] to A such that t -* d and the elements of C are mapped to themselves. By [4, Cor. 2.6] this is an isomorphism and A = C[t,s,a] for some a in R as asserted.

Remark: Derivations satisfying the hypothesis C[a] = End_\text{R}(C) exist. For example if C admits a p-basis u_i, 1 < i < r over R, then the R derivation on C given by QU_i = 1,

\[ a^i = \text{a}^i - \text{a}^i \cdot \text{d}^i \cdot \text{a} - \text{a}^i \cdot \text{d}^i \text{a}, \quad i > 1 \]
satisfies the above relation. [11, Lemma 7]

Recall [4, p. 38] that two Azumaya R algebras A and A_2 with splitting subalgebra C are isomorphic under an admissible isomorphism if A : A_1 -> A_2 is an isomorphism such that it is the identity on C. From here on until the end of this section, assume the hypothesis of theorem 3.2; that is, C is a commutative R algebra with 3 a derivation of C such that Ker S = R and C is finitely generated projective as an R module with End_\text{R}(C) = C[a].

The next theorem classifies admissible isomorphism classes of Azumaya R algebras containing C as a splitting subalgebra.

Theorem 3.5. The Azumaya R algebras C[t^S,a^-] and C[t_\text{a},3,a_\text{a}^1] are isomorphic under an admissible isomorphism if and only if

\[ a_1 = a_2 \] for some \text{leC}.

Proof: Assume a : C[t,3,a\_l] -> C[t,B,a\_2] is an admissible
isomorphism. Since \([v(t), c] = [a(t), cr(c)] = cr(t, c) = a(S(c)) = a(c)\)
we have \([cr(t)-t, c] = 0\) for all \(c\) in \(C\). Hence \(a(t) = t + I\)
for some \(-teC\). In particular \(a_1 = cr(X(t)) = X(a(t)) = X(t + ^^) = X(t) + 6 (I) =
= a_1 + 6(t)\) and thus \(a_1 - a_2 = 6(f)\). Conversely it is clear
that if \(a_1 - a_2 \equiv Mf\) the correspondence \(t \mapsto t + I\) determines a
well defined ring homomorphism \(a\) from \(C[t, a_1, a_2]\) to \(C[t, a_1, a_2]\)
which is the identity on \(C\). By [4, Cor. 2.6] \(a\) is an admissible
isomorphism.

The last theorem in this section deals with the multiplication
in the abelian group \(A(C^R)\) of equivalence classes of Azumaya \(R\)
algebras containing \(C\) as a splitting subalgebra. We refer the
reader to [4, p.41] for the relevant definitions and further details.

**Theorem 3.6.** \(C[t^s, a_1] \cdot C[t^s, a_2] = C[t^s, a_1, a_2]\) where \(\cdot\)
denotes the product in the group \(A(C^R)\).

**Proof:** Set \(A^1 = C[t, a_1]\), \(A_2 = C[t, a_2]\). By [4, p.41]

\[
A_1 \cdot A_2 = \text{End}_{A^1 \otimes A_2} A_2 \otimes C \cdot A^2 \subset \text{the product of } A_1 \text{ and } A_2
\]
in \(A(C^R)\) where both \(A_1\) and \(A_2\) are viewed as left \(C\) modules,
and \(A_1 \otimes C \cdot A_2\) as a right \(A^1 \otimes A_2\) module. The product \(A_1 \cdot A_2\)
is an Azumaya \(R\) algebra and the injection \(C \rightarrow \text{End}_{A^1 \otimes A_2} (A_1 \cdot A_2)\)
given by \(c \rightarrow c \otimes L(c \otimes 1)\) embeds \(C\) as a splitting subalgebra of \(A_1 \cdot A_2\).

Define \(\phi : C[t^s] \rightarrow \text{End}_{A^1 \otimes A_2} (A_1 \cdot A_2)\) by \(\phi(c) = L(c \otimes 1)\) for all \(c\)
in \(C\) and \(\phi(t) = L(t \otimes 1 + 1 \otimes t)\). It is easy to see that
\(\phi(t) \in \text{End}_{A^1 \otimes A_2} (A_1 \otimes A_2)\) if and only if \(\phi(t)(l \otimes c) = \phi(t)(c \otimes l)\)
for all \(c\) in \(C\) since \(l \otimes c = c \otimes l\) in \(A_1 \otimes C \cdot A_2\). But
\(\phi(t) \circ L(1 \otimes c) = \phi(t) \circ L(c \otimes l) = t \otimes c + ietx: -tc \otimes l - c \otimes t = (ct - tc) \otimes l +
+ l \otimes (tc - ct) = L[a(c) \otimes l] = \phi(c(a(c)). Hence \(\phi\) is a well defined
ring homomorphism. Finally \(\phi(X(t)) = X(\phi(t)) = X(L(t \otimes 1 + l \otimes t) =
= Lta \cdot 1 + 1 \otimes a_2) = L[(a + a_2) \otimes l] = \phi(a^1 + a_2) \cdot \text{ hence } \phi\) extends to
a homomorphism.
Corollary 3.7. $A(C,R) \cong R'/b(C^*)$. If $P(C)$ denotes the group of isomorphism classes of projective $C$ modules of rank 1 and $P(C) = 0$; then $B(C/R) \cong R^+/6C^+$, where $B(C/R)$ denotes the Brauer group of Azumaya $R$ algebras split by $C$. Proof: Theorem 3.2 and Theorem 3.6 define an onto group homomorphism from $R^+$ to $A(C^R)$ via $a^a \rightarrow C[t,j\cdot x]$. The kernel of this homomorphism is $8(C^+)$ by Theorem 3.5. The last statement of the theorem follows from the fact that if $P(C) = 0$ then $B(C/R) \cong A(C,R)$. [4, Prop. 2.13].

Remarks: In the case that $R$ is field of characteristic $p$ and $C$ a purely inseparable extension of exponent 1 the above results appear in Hoechsmann [6], and Jacobson [7],[8]. Our proofs follow theirs with minor changes.
